Lecture 17. Temperature Lidar (6)

Integration Technique

- Review Doppler and Boltzmann techniques
- Integration technique for temperature
- Searchlight integration lidar
- Rayleigh integration temperature lidar
- Vibrational Raman integration lidar
- Falling sphere temperature measurement
- Rayleigh/Raman lidar instrumentation
- Summary
Doppler effect and Boltzmann distribution are two effects that are directly temperature-dependent. The Doppler technique and Boltzmann technique are “straight-forward” in the sense of deriving temperature or wind. However, the lidar architecture is usually complicated and sophisticated, due to the high demands on frequency accuracy and tuning, laser linewidth, and laser power etc.

\[ \frac{N_2}{N_1} = \frac{g_2}{g_1} \exp\left\{ -\frac{(E_2 - E_1)}{k_B T} \right\} \]

\[ T = \frac{\Delta E / k_B}{\ln\left( \frac{g_2}{g_1} \cdot \frac{N_1}{N_2} \right)} \]
Integration Technique

- The hydrostatic equation
  \[ \frac{dP(z)}{dz} = -\rho(z)g(z) \]

- Ideal gas law
  \[ P(z) = \frac{\rho(z)RT(z)}{M(z)} \]

- Integration from the upper altitude yields
  \[ T(z) = T(z_0) \frac{\rho(z_0)}{\rho(z)} \frac{M(z)}{M(z_0)} + \frac{M(z)}{R} \int_{z_0}^{z} \frac{\rho(z')g(z')}{P(z)} dz' \]

\( T(z) = \) atmospheric temperature profile (K)
\( P(z) = \) atmospheric pressure profile (mbar)
\( \rho(z) = \) atmospheric mass density profile (kg/m\(^3\))
\( g(z) = \) gravitational acceleration (m/s\(^2\))
\( M(z) = \) mean molecular weight of the atmosphere
\( R = \) universal gas constant (8.31432 J/mol/K))
\( z_0 = \) altitude of the upper level starting temperature (m)
Integration Technique

- Atmosphere mass density vs number density
  \[ \rho(z) = \frac{n(z)M(z)}{N_A} \]
  where \( N_A \) is the Avogadro constant

- Thus, we have
  \[ T(z) = T(z_0) \frac{n(z_0)}{n(z)} + \frac{M(z)}{R} \int_{z_0}^{z} \frac{n(z')M(z')g(z')}{n(z)M(z)} \, dz' \]

- Below 100 km for the well-mixed atmosphere, we have \( M(z) = M(z') \), so they cancel out in the integration
  \[ T(z) = T(z_0) \frac{n(z_0)}{n(z)} + \frac{M(z)}{R} \int_{z}^{z_0} \frac{n(z')g(z')}{n(z)} \, dz' \]

- Number density ratio (relative number density)
  \( \Rightarrow \) Temperature profile
The uncertainty is determined by the photon noise and upper altitude temperature $T(z_0)$. The variance of derived temperature is given by

$$\text{var}[T(z)] \approx \frac{T^2(z)}{N_R(z)} + \left\{ \text{var}[T(z_0)] + \frac{T^2(z_0)}{N_R(z_0)} \right\} \exp\left[-2(z_0 - z)/H\right]$$

After 1–2 scale height, the error introduced by $T(z_0)$ is not important anymore. So the temperature error is mainly determined by the photon counts and their noise.

The key is how to measure atmosphere (relative) density with high accuracy and precision. Different approaches can be applied, not limited to pulsed lidar technique.
From Searchlight to Rayleigh, Raman & Falling Sphere

- Integration temperature technique relies on the assumptions of hydrostatic equilibrium equation and ideal gas law in atmosphere. It involves integrating the atmosphere relative density profile downward using a starting temperature at an upper altitude.

- It was pioneered by Elterman [1951, 1953, 1954] with cw searchlight to measure stratospheric density thus deriving temperature in 1950s.

- The use of high power lasers with the Rayleigh lidar in the atmosphere region (30-100 km) free of aerosol and fluorescence was pioneered by Hauchecorne and Chanin [1980] (French group).

- In the lower atmosphere where aerosol scattering contaminates Rayleigh scattering, Keckhut et al. [1990] developed Raman lidar to measure atmosphere density from vibrational Raman scattering and then derive temperature below 30 km.

- Inflatable falling sphere provides high-precision atmosphere density thus temperature measurements [Schmidlin et al., 1991].

Searchlight Integration Lidar

\[ I_{\text{scatter}} \propto n_{\text{atmos}} \]

Bistatic Configuration

[Elterman, JGR, 1954]
In the atmosphere region free of aerosols and fluorescence, the lidar return photon counts are given by

\[ N_S(\lambda, z) = \left( \frac{P_L(\lambda) \Delta t}{hc/\lambda} \right) \left( \beta_{Rayleigh}(z) \Delta z \right) \left( \frac{A}{z^2} \right) T_a^2(\lambda, z)(\eta(\lambda)G(z)) + N_B \]

where Rayleigh backscatter coefficient is proportional to atmosphere number density

\[ \beta_{Ray}(z) = \sigma_{Ray}(\pi, \lambda) n_a(z) \]

Thus, ratio of normalized photon counts gives the atmosphere relative density information

\[ \frac{N_S(z_1) - N_B}{N_S(z_2) - N_B} \frac{z_1^2}{z_2^2} = \frac{n_a(z_1)}{n_a(z_2)} \]

\textbf{Lidar Backscatter Ratio} \Rightarrow \textbf{Relative Density} \Rightarrow \textbf{Temperature (at different altitudes)} \quad \text{(Rayleigh)}

Raman Scattering of N$_2$ and O$_2$

Raman shift amount is independent of incident laser wavelength.

Fig. 9.1. Vibration–rotation energy levels of the N$_2$ molecule, Raman transitions, and resulting spectrum.

☐ Raman shift amount is independent of incident laser wavelength
Raman Integration Lidar

- In the lower atmosphere region where aerosols present Rayleigh scattering returns are contaminated by aerosol Mie scattering, so cannot be used in the integration technique.
- However, Raman scattering only comes from molecules, thus, free of aerosol influence. By detecting Raman scattering at a different wavelength (e.g., 607 nm compared to 532 nm), Mie and Rayleigh contamination are avoided.

\[
N_S(\lambda, \lambda_L, z) = \left( \frac{P_L(\lambda_L) \Delta t}{hc/\lambda_L} \right) \left( \sigma_{\text{Raman}}(\lambda_L, \lambda, z)n_{N_2}(z)\Delta z \right) \\
\times \left( \frac{A}{z^2} \right) T_a(\lambda_L, z)T_a(\lambda, z)(\eta(\lambda_L)\eta(\lambda)G(z)) + N_B
\]

Lidar Backscatter Ratio $\Rightarrow$ Relative Density $\Rightarrow$ Temperature (at different altitudes) (Raman)
Rayleigh-Raman Integration Lidar

Fig. 2. Lidar temperature profiles compared with the corresponding CIRA 1988 model (dashed lines): (A) 09/11/88, 19H03 06H17; (B) 08/02/89, 18H26 06H13; (C) 14/04/89, 21H05 23H56.
Inflatable Falling Sphere

Rocket transports a metal sphere to upper atmosphere

After release the sphere inflates to 1-m metal sphere falling through atmosphere

High-precision radar tracks sphere position & acceleration

Input to the equation of motion of the falling sphere to derive atmosphere density

Integration from top to derive temperature from density data

Falling Sphere Temperature

Rothera 1998
Rayleigh/Raman Lidar Instrumentation

- Typical Rayleigh/Raman temperature lidar utilizes the commercial Nd:YAG laser system as it provides robust laser power and operation (usually broadband).
- Any (short wavelength) resonance fluorescence lidar, like Fe Boltzmann lidar, also functions as a Rayleigh lidar in the region free of aerosol and fluorescence (about 30–75 km).
- Rayleigh scattering is inversely proportion to the 4th power of wavelength. So the shorter the wavelength, the stronger the Rayleigh scattering, as long as atmosphere absorption is not too strong.
- Operating in deep Fraunhofer lines will benefit daytime operation to reduce the solar background.
- Availability and robustness of laser systems are another consideration in lidar design.

Summary

- **Integration technique** relies on the assumptions of hydrostatic equilibrium and ideal gas law in the atmosphere interested. It involves integrating the atmosphere relative density profile downward using a starting temperature (usually coming from a model or independent measurement) at an upper altitude.

- The key is to somehow measure the atmosphere relative number density with high precision and unbiased.

- Integration technique started with cw searchlight in 1950s, dramatically enhanced by high-power pulsed Rayleigh lidar in 1980s for region free of aerosols, further developed by vibrational Raman lidar in 1990s for region with aerosols.

- Inflatable falling sphere released by rocket is another perfect example for integration temperature technique.
