Lecture 22. Lidar Error and Sensitivity Analysis (1)

- Introduction
- Accuracy versus Precision
- Accuracy in lidar measurements
- Precision in lidar measurements
- Propagation of errors vs. differential method
- Derivation of Errors
Introduction

- Before going further, let us rule out one kind of errors – illegitimate errors that originate from mistakes in measurement or computation.

- Have you heard about the measurement of “faster-than-light neutrinos”, announced in September 2011?

-- It is totally due to a bad error in the experiments: wrong measurement of time of flight! The experiments were also badly designed – using GPS instead of atomic clock to count the time!

http://news.sciencemag.org/scienceinsider/2012/02/breaking-news-error-undoes-faster.html

Accuracy versus Precision

- It is important to distinguish between the terms accuracy and precision, because in error analysis, accuracy and precision are two different concepts, describing different aspects of a measurement.

- The accuracy of an experiment is a measure of how close the result of the experiment is to the true value.

- The precision is a measure of how well the result has been determined, without reference to its agreement with the true value. The precision is also a measure of the reproducibility of the result in a given experiment.

- Accuracy concerns about bias, i.e., how far away is the measurement result from the true value? Precision concerns about uncertainty, i.e., how certain or how sure are we about the measurement result?

- For any measurement, the results are commonly expected to be a mean value with a confidence range: $x_i \pm \Delta x_i$
Illustration of Accuracy and Precision

**FIGURE 1.1**
Illustration of the difference between precision and accuracy. (a) Precise but inaccurate data. (b) Accurate but imprecise data. True values are represented by the straight lines.

[Data Reduction and Error Analysis, Bevington and Robinson, 2003]
Classification of Measurement Errors

- Measurement errors are classified into two major categories: Systematic errors and random errors.

- Systematic errors are errors that will make our results different from the “true” values with reproducible discrepancies. Errors of this type are not easy to detect and not easily studied by statistical analysis. They must be estimated from an analysis of the experimental conditions, techniques, and our understanding of physical interactions. A major part of the planning of an experiment should be devoted to understanding and reducing sources of systematic errors.

- Random errors are fluctuations in observations that yield different results each time the experiment is repeated, and thus require repeated experimentation to yield precise results.

- Another way to describe systematic and random errors are: Experimental uncertainties that can be revealed by repeating the measurements are called random errors; those that cannot be revealed in this way are called systematic errors.
Illustration of Accuracy and Precision

Figure 4.1. Random and systematic errors in target practice. (a) Because all shots arrived close to one another, we can tell the random errors are small. Because the distribution of shots is centered on the center of the target, the systematic errors are also small. (b) The random errors are still small, but the systematic ones are much larger—the shots are "systematically" off-center toward the right. (c) Here, the random errors are large, but the systematic ones are small—the shots are widely scattered but not systematically off-center. (d) Here, both random and systematic errors are large.
Illustration of Accuracy and Precision

Figure 4.2. The same experiment as in Figure 4.1 redrawn without showing the position of the target. This situation corresponds closely to the one in most real experiments, in which we do not know the true value of the quantity being measured. Here, we can still assess the random errors easily but cannot tell anything about the systematic ones.
Errors vs. Accuracy & Precision

- The accuracy of an experiment is generally dependent on how well we can control or compensate for systematic errors. How well the assumptions made are close to reality will affect accuracy.
- The precision of an experiment depends upon how well we can overcome random errors.
- A given accuracy implies an equivalent precision and, therefore, also depends on random errors to some extent.

Accuracy in Lidar Measurements

- Systematic errors determine the measurement accuracy. Assumptions made in data retrieval can also contribute to inaccuracy.
- Accuracy is mainly determined by:

1. How much we understand the physical interactions and processes involved in the measurements or observations, e.g., atomic parameters and absorption cross-sections, isotopes, branching ratios, Hanle effect, atomic layer saturation effect, transmission/extinction, interference absorption, etc., are key to resonance fluorescence, DIAL, Raman, and fluorescence lidars. For laser range finder and altimeter, whatever the factors influencing the time of flight will affect the accuracy, e.g., multiple scattering, distortion in the return signal shape, etc.

2. How well we know the lidar system parameters, e.g., laser central frequency, laser linewidth and lineshape, photo detector/discriminator calibration, receiver filter function, overlapping function, chopper function, etc.
Accuracy in Lidar Measurements

- It happened in the history of physical experiments (e.g., quantum frequency standard) that when people understood more about the physical processes or interactions, the claimed experimental accuracy decreased. This is because some systematic errors (bias) caused by certain interactions were not included in earlier error analysis, as people were not aware of them. This could also happen to lidar measurements.

- For secondary atomic clocks, they can compare with the primary clocks to determine their accuracies. But how will the primary clocks’ accuracies be determined?

  -- Inter-comparisons among primary clocks and then detailed analyses of all possible physical interactions. Very challenging!!!

- In the following lectures on different types of lidars, keep in mind such a question: What affects the measurement accuracy for any lidars?
Systematic bias of temperature measurements can be caused by ignoring the branching ratio in the Fe Boltzmann lidar.

Atomic Fe Energy Level

[Helbwachs, 1994; Chu et al., 2002]
Fe Boltzmann Temperature Ratio

Fe resonance fluorescence lidar equation

\[ N_{Fe}(\lambda, z) = \left( \frac{P_L(\lambda) \Delta t}{hc/\lambda} \right) \left[ \sigma_{eff}(\lambda, \sigma_L, T, v_R) R_{B\lambda} n_{Fe}(z) \right] \Delta z \left( \frac{A}{4\pi z^2} \right) \left( T_a^2(\lambda) T_c^2(\lambda, z) \right) (\eta(\lambda) G(z)) \] (10.1)

Rayleigh scattering lidar equation at Rayleigh-normalization altitude \( z_R \)

\[ N_R(\lambda, z_R) = \left( \frac{P_L(\lambda) \Delta t}{hc/\lambda} \right) \left[ \sigma_R(\pi, \lambda) n_R(z_R) \right] \Delta z \left( \frac{A}{z_R^2} \right) T_a^2(\lambda, z_R) (\eta(\lambda) G(z_R)) \] (10.2)

Rayleigh normalization leads to normalized photon counts

\[ N_{Norm}(\lambda, z) = \frac{N_{Fe}(\lambda, z)}{N_R(\lambda, z_R)} \frac{1}{T_c^2(\lambda, z) z_R^2} = \frac{\sigma_{eff}(\lambda, \sigma_L, T, v_R) R_{B\lambda} n_{Fe}(\lambda, z)}{\sigma_R(\lambda) n_R(\lambda, z_R)} \] (10.3)

Take the Boltzmann temperature ratio as

\[ R_T(z) = \frac{N_{norm}(\lambda_{374}, z)}{N_{norm}(\lambda_{372}, z)} = \frac{g_2}{g_1} \frac{R_{B374}}{R_{B372}} \left( \frac{\lambda_{374}}{\lambda_{372}} \right)^{4.0117} \frac{\sigma_{eff}(\lambda_{374}, \sigma_{L374}, T, v_R)}{\sigma_{eff}(\lambda_{372}, \sigma_{L372}, T, v_R)} \exp(-\Delta E / k_B T) \] (10.4)

Therefore, temperature can be derived as

\[ T(z) = \frac{\Delta E / k_B}{\ln \left[ \frac{g_2}{g_1} \frac{R_{B374}}{R_{B372}} \left( \frac{\lambda_{374}}{\lambda_{372}} \right)^{4.0117} \frac{\sigma_{eff}(\lambda_{374}, \sigma_{L374}, T, v_R)}{\sigma_{eff}(\lambda_{372}, \sigma_{L372}, T, v_R)} \frac{1}{R_T(z)} \right]} \] (10.5)
Accuracy in Lidar Measurements

- In the DIAL, if some interference gases were unknown to people thus were not considered or compensated in data reduction, bias could be resulted.

- In Rayleigh integration lidars, the major issues affecting accuracy would be the photo detector/discriminator calibration (saturation), overlapping, chopper, and filter functions, interference from aerosol scattering, and atmosphere constant change in the upper atmosphere when air is NOT well mixed.

- In Raman lidars, how well we know the Raman scattering cross-section, filter function (determine how many Raman lines are detected), aerosol interference, etc would affect the accuracy.

- In high-spectral resolution lidar, how well we know the spectral analyzer and how stable the spectral analyzer is, will affect the accuracy and long-term stability.

- If we do not know our lidar parameters well, bias could also be resulted, e.g., the chirp issue in Na, K, or Fe Doppler lidar due to pulsed amplification. If we were not aware of PMT and discriminator saturation issue, systematic bias could result from our ignorance. If we couldn’t measure the narrowband filter function well for daytime observations, systematic errors would occur.

- For horizontal wind measurements, how accurate we know the off-zenith angle and the azimuth angle would also affect our measurement accuracy.
Possible Errors or Biases

1) Laser freq locking error, 2) pulsed laser freq chirp, 3) laser line shape and linewidth, 4) Hanle effect, 5) metal layer saturation, etc. ...
Error Analysis: Accuracy

- Systematic errors determine the measurement accuracy.
- Possible sources: imprecise information of (1) atomic absorption cross-section, (2) laser absolute frequency calibration, (3) laser lineshape, (4) receiver filter function, (5) photo detector calibration, (6) geometric factor, (7) interference gases and aerosols, (8) pressure broadening ...
- Determination of $\sigma_{abs}(\nu)$: QM calculation, convolution of Gaussian with Lorentzian, Hanle effect, Na layer saturation, and optical pumping effect.

Hanle effect modified $A_n$:
5, 5, 2, 14, 5, 1 →
5, 5.48, 2, 15.64, 5, 0.98

- Absolute laser frequency calibration and laser lineshape.
- Receiver filter function and geometric factor.
- Photon detector and discriminator calibration

Na Layer Saturation
Accuracy in Lidar Measurements

- For lidar researchers, one of our major tasks is to understand the physical processes as good as possible (e.g., measuring atomic parameters accurately from lab experiments, seeking and understanding all possible physical interactions involved in the scattering or absorption and fluorescence processes like saturation effects, understanding the details of laser and detection process) and improve our experimental conditions to either avoid or compensate for the systematic errors.

- These usually demand experimenters to be highly knowledgeable of atomic, molecular, and laser physics and spectroscopy, measurement procedure, etc. That’s why we emphasize the spectroscopy knowledge is more fundamental to lidar technology advancement, rather than optical/laser engineering.

- Achieving high accuracy also requires experimenters to control and measure the lidar parameters very accurately and precisely. -- Easy to say but difficult to do. Calibrating your measurement tools is also very important.

- On the lidar design aspect, it would be good to develop lidar systems that are stable and less subject to laser frequency drift or chirp, etc.

- Also, sometimes it is necessary to take the trade-off between accuracy and precision, depending on the experimental purposes/goals.
Laser Lineshape and Frequency Chirp

[Chu et al., ILRC, 2010]

[She et al., Appl. Opt., 1992]
Accuracy in Lidar Measurements

- Absolute temperature and wind values are the most difficult quantities to measure in lidar field, while relative perturbations are much easier to determine.

- In lidar observations of atmosphere, the situation is more complicated as the atmosphere also experiences large geophysical variability. The geophysical variability can sometimes cover the accuracy problems of lidar measurements, and also makes the estimation of accuracy very difficult to perform.

- Inter-instrument comparison (i.e., comparison between different lidars or between lidars and other instruments in common volume and simultaneous measurements) may be necessary in the assessment of lidar measurement accuracy. However, currently most people do not pay attention to the accuracy assessment, probably due to lack of knowledge or lack of funding and time.

- For students taking this class, you should be at least aware of these issues and keep them in mind when you design and/or use a lidar system or lidar data.

- Old words say “People with less knowledge are more confident” or “Compound ignorance”. But I would rather have that you are less confident about the results with more knowledge and awareness of accuracy issues.

- Of course, the ultimate goal is to enhance our knowledge to improve accuracy or compensate systematic errors so that we are both very knowledgeable and confident in our measurement results.
Error Analysis: Precision

- Random errors determine the measurement precision.
- Possible sources: (1) shot noise associated with photon-counting system, (2) random uncertainty associated with laser jitter and electronic jitter. The former ultimately limits the precision because of the statistic nature of photon-detection processes.

- In normal lidar photon counting, photon counts obey Poisson distribution. Therefore, for a given photon count $N$, the corresponding uncertainty is

$$\Delta N = \sqrt{N}$$

- For three-frequency technique, the relative errors of $R_T$ and $R_W$ introduced by photon noise are (see later slides for derivation)

$$\frac{\Delta R_T}{R_T} = \frac{1 + \frac{1}{R_T}}{(N_{f_a})^{1/2}} \left[ 1 + \frac{B}{N_{f_a}} \left( \frac{1 + \frac{2}{R_T^2}}{1 + \frac{1}{R_T}} \right) \right]^{1/2}$$

$$\frac{\Delta R_W}{R_W} = \frac{1 + \frac{1}{R_W}}{(N_{f_a})^{1/2}} \left[ 1 + \frac{B}{N_{f_a}} \left( \frac{1 + \frac{1}{R_W^2}}{1 + \frac{1}{R_W}} \right) \right]^{1/2}$$
Precision in Lidar Measurements

- Precision is usually concerned with the random errors - errors that can be reduced by more repeated measurements or errors that can be reduced by sacrificing temporal or spatial resolutions.

- By making many times of the same measurements and then taking the mean of all measurements, the random errors of the measurements can be reduced. For example, when we measure the radiative lifetime of an atom through measuring the decay time, one measurement will certainly have some uncertainty. By repeating the measurements several times under the same experimental conditions, we can reduce the uncertainty.

- In lidar detection of atmosphere, we may not really repeat the “same” measurements as atmospheric conditions may never repeat. But we certainly can make more measurements under similar conditions. The accumulation of more lidar shots is equivalent to repeating the same measurements to reduce uncertainties caused by photon noise, laser frequency jitter, and linewidth fluctuation. In such a case, we basically sacrifice the temporal or spatial resolution to improve precision.
Photon noise is the major limitation to measurement precision. From the error equation, we know the larger the signal photon counts, the smaller the error caused by photon noise. Why so?

A single shot results in a photon count of $N$ with fluctuation of $\Delta N$, leading to an error of $\Delta N/N$. When many ($m$) shots are integrated together, we have the photon counts roughly $mN$ with fluctuation of $\Delta(mN)$, leading to the error of $\Delta(mN)/mN$. This error should have been reduced if we regard this integration procedure as taking a mean of repeated measurements.

\[
\frac{\Delta(mN)}{mN} = \sqrt{\frac{mN}{mN}} = \frac{1}{\sqrt{m}} \cdot \frac{\sqrt{N}}{N} = \frac{1}{\sqrt{m}} \cdot \frac{\Delta N}{N}
\]

Therefore, the precision error caused by photon noise can be improved by several ways: (1) sacrifice of temporal resolution by integrating more shots together; (2) sacrifice of spatial resolution by integrating more range bins together; or the combination of both; (3) increase the photon count of single shot lidar pulse.
Precision in Lidar Measurements

- The precision errors caused by the random error sources like laser frequency jitter, linewidth fluctuation, and electronic jitter can be improved by integrating more shots together - sacrifice of temporal resolution, but may not be improved by integrating bins.

- Random error sources could lead to both random and systematic measurement errors. For example, laser central frequency jitter in the 3-freq ratio technique can lead to warm temperature bias (systematic error) in addition to random errors.

- The differentiation of metric ratio method described in later slides can apply to both systematic and random errors, depending on the nature of the errors. Error sources could be systematic bias or random jitter, and measurement errors could also be systematic or random errors.

- For example, the chirp in $f_a$ is a systematic error source if it is not counted, while the jitter in $f_a$ is a random error.
Propagation of Errors

- Propagation of Errors is an important aspect in lidar error analysis. This is because the temperature, wind, backscatter coefficient, etc. that we want to determine are dependent variables that are a function of one or more different measured variables (e.g., photon counts, laser frequency and linewidth). We must know how to propagate or carry over the uncertainties in the measured variables to determine the uncertainty in the dependent variables.

- For example, photon noise causes the uncertainty in the measured photon counts, then the photon count uncertainty leads to the uncertainty in the temperature and wind ratios $R_T$ and $R_W$, which will result in errors in the inferred temperature $T$ and wind $W$. -- Error propagation procedure

- Basic rules for propagation of error can be found in many textbooks, e.g., addition, subtraction, multiplication, division, product of power, and mixture of them, along with many other complicated functions.

- We will introduce a universal procedure through the use of differentials of the corresponding ratios $R_T$ and $R_W$ as illustrated below. This method is mathematically based on the Taylor expansion.
Error Analysis Procedure

- We use the temperature error derivation for 3-freq Na lidar as an example to explain the error analysis procedure using a differentiation method.

- For 3-frequency technique, we have the temperature ratio

\[ R_T = \frac{\sigma_{\text{eff}}(f_+) + \sigma_{\text{eff}}(f_-)}{\sigma_{\text{eff}}(f_a)} = \frac{N(f_+) + N(f_-)}{N(f_a)} \]

- Through this ratio \( R_T \) or further through the effective cross-section, the temperature \( T \) is an implicit function of \( R_T \), laser frequencies \( f_a, f_+, f_- \), laser linewidth \( \sigma_L \), radial wind, etc. Each parameter could have some uncertainty or error, leading to errors in the measured temperature.

- Therefore, the temperature error is given by the derivatives

\[ \Delta T = \frac{\partial T}{\partial R_T} \Delta R_T + \frac{\partial T}{\partial f_a} \Delta f_a + \frac{\partial T}{\partial f_\pm} \Delta f_\pm + \frac{\partial T}{\partial \sigma_L} \Delta \sigma_L + \frac{\partial T}{\partial V_R} \Delta V_R + \text{higher-order terms} \]
Differentiation Method

- The root-mean-square (rms) temperature error is given by

\[
(\Delta T)_{\text{rms}} = \sqrt{\left( \frac{\partial T}{\partial R_T} \Delta R_T + \frac{\partial T}{\partial f_a} \Delta f_a + \frac{\partial T}{\partial f_\pm} \Delta f_\pm + \frac{\partial T}{\partial \sigma_L} \Delta \sigma_L + \frac{\partial T}{\partial v_R} \Delta v_R \right)^2}
\]

- If the error sources are independent from each other, then the means of cross terms are zero. Then we have

\[
(\Delta T)_{\text{rms}} = \sqrt{\left( \frac{\partial T}{\partial R_T} \right)^2 + \left( \frac{\partial T}{\partial f_a} \right)^2 + \left( \frac{\partial T}{\partial f_\pm} \right)^2 + \left( \frac{\partial T}{\partial \sigma_L} \right)^2 + \left( \frac{\partial T}{\partial v_R} \right)^2}
\]

- The above error equation indicates that many laser parameters and radial wind errors could affect the inferred temperature because they all influence the effective cross sections. In the meantime, photon noise can cause uncertainty in the ratio \( R_T \), resulting in temperature error.
Error Derivation: Implicit Differentiation

How to derive the error coefficients, like $\frac{\partial T}{\partial R_T}$, $\frac{\partial T}{\partial f_a}$, etc.?

We may use the implicit differentiation through $R_T$ as below:

$$\Delta T = \Delta R_T \left( \frac{\partial R_T}{\partial R_T} / \frac{\partial R_T}{\partial T} \right) + \Delta f_a \left( \frac{\partial R_T}{\partial f_a} / \frac{\partial R_T}{\partial T} \right) + \Delta f_\pm \left( \frac{\partial R_T}{\partial f_\pm} / \frac{\partial R_T}{\partial T} \right)$$

$$+ \Delta \sigma_L \left( \frac{\partial R_T}{\partial \sigma_L} / \frac{\partial R_T}{\partial T} \right) + \Delta v_R \left( \frac{\partial R_T}{\partial v_R} / \frac{\partial R_T}{\partial T} \right)$$

For the photon-noise induced temperature error,

$$\Delta T = \frac{1}{\partial R_T / \partial T} \cdot \Delta R_T = \frac{R_T}{\partial R_T / \partial T} \cdot \frac{\Delta R_T}{R_T} = \frac{1}{S_T} \cdot \Delta R_T$$

where $S_T$ is called the sensitivity of $R_T$ to temperature $S_T = \left( \partial R_T / \partial T \right) / R_T$

The relative error of $R_T$ can be derived in terms of measured signal and background photon counts (see later slides).
Derivation of Error Coefficients

- The temperature error coefficient can be derived numerically

\[
\frac{R_T}{\partial R_T / \partial T} = \frac{R_T}{[R_T(T + \delta T) - R_T(T)]/\delta T}
\]

- Two approaches to derive the above numerical solution:

  (1) One way is to use the equation of \( R_T \) in terms of cross sections. You don't have to go through the entire simulation process each time when you change the temperature, but just calculate the \( R_T \) from the effective cross section.

  \[
  R_T = \frac{\sigma_{\text{eff}}(f_+,T) + \sigma_{\text{eff}}(f_-,T)}{\sigma_{\text{eff}}(f_a,T)}
  \]

  (2) Another way is to use the equation of \( R_T \) in terms of photon counts, and then go through the entire simulation procedure to re-compute \( R_T \) for each new temperature. This method is more universal than the first approach, because not all cases could have a \( R_T \) written in terms of pure physical cross sections.

  \[
  R_T = \frac{N(f_+,T) + N(f_-,T)}{N(f_a,T)}
  \]
Derivation of $\Delta R_T / R_T$

We use 2-freq ratio technique of Na lidar as an example to derive the relative error $\Delta R_T / R_T$.

2-freq temperature ratio is defined as

$$R_T = \frac{N_{f_c}}{N_{f_a}} \quad (1)$$

Using differentiation method, we have

$$\Delta R_T = \frac{\partial R_T}{\partial N_{f_c}} \Delta N_{f_c} + \frac{\partial R_T}{\partial N_{f_a}} \Delta N_{f_a} = \frac{1}{N_{f_a}} \Delta N_{f_c} - \frac{N_{f_c}}{N_{f_a}^2} \Delta N_{f_a} \quad (2)$$

Combining Eq. (1) with Eq. (2), we have

$$\frac{\Delta R_T}{R_T} = \frac{\Delta N_{f_c}}{N_{f_c}} - \frac{\Delta N_{f_a}}{N_{f_a}} \quad (3)$$

Regarding the errors from two frequencies are uncorrelated, we have

$$\left( \frac{\Delta R_T}{R_T} \right)_{rms} = \sqrt{ \left( \frac{\Delta N_{f_c}}{N_{f_c}} \right)^2 + \left( \frac{\Delta N_{f_a}}{N_{f_a}} \right)^2} \quad (4)$$

Considering the signal photon counts are derived by subtracting the background counts from the total photon counts, the photon count uncertainty is given by

$$\left( \Delta N_{f_c} \right)^2 = N_{f_c} + B, \quad \left( \Delta N_{f_a} \right)^2 = N_{f_a} + B \quad (5)$$
Derivation of $\Delta R_T / R_T$ Cont’d

- Substituting Eq. (5) into Eq. (4) and considering Eq. (1), we obtain

$$\left(\frac{\Delta R_T}{R_T}\right)_{rms} = \sqrt{\frac{N_{f_c} + B}{N_{f_c}^2} + \frac{N_{f_a} + B}{N_{f_a}^2}} = \sqrt{\frac{R_T N_{f_a} + B}{(R_T N_{f_a})^2} + \frac{N_{f_a} + B}{N_{f_a}^2}}$$  \hspace{1cm} (6)

- Some algebra derivation leads us to the final result

$$\left(\frac{\Delta R_T}{R_T}\right)_{rms} = \left(\frac{1 + \frac{1}{R_T}}{N_{f_a}}\right)^{1/2} \left[1 + \frac{B}{N_{f_a}} \left(\frac{1 + \frac{1}{R_T^2}}{1 + \frac{1}{R_T}}\right)\right]^{1/2}$$  \hspace{1cm} (7)

- If we change the expression to SNR of the peak frequency channel, then we have an approximate expression as below:

$$\left(\frac{\Delta R_T}{R_T}\right)_{rms} \approx \frac{1}{\text{SNR}_{f_a}} \sqrt{1 + \frac{1}{R_T}}$$  \hspace{1cm} (8)

where SNR is defined as

$$\text{SNR}_{f_a} \equiv \frac{N_{f_a}}{\Delta N_{f_a}} = \frac{N_{f_a}}{\sqrt{N_{f_a} + B}}$$  \hspace{1cm} (9)
Temperature Error Due to Photon Noise

- Integrating above equations together, we obtain the equation for the temperature error caused by photon noise as below:

\[ \Delta T = \frac{R_T}{\partial R_T / \partial T} \cdot \frac{\Delta R_T}{R_T} \]

\[ = \frac{R_T}{[R_T(T + \delta T) - R_T(T)] / \delta T} \cdot \left( \frac{1 + \frac{1}{R_T}}{N_{f_a}} \right)^{1/2} \left[ 1 + \frac{B}{N_{f_a}} \left( \frac{1 + \frac{2}{R_T^2}}{1 + \frac{1}{R_T}} \right) \right]^{1/2} \]

- The photon counts in the above equation can be written in terms of signal to noise ratio (SNR), if it is more convenient or desirable for some analyses.
